React Native Challenge: Mini Shop

Build a small shopping app over a couple of days. The aim is to practise React Native navigation, reusable components and Redux Toolkit without getting bogged down in backend work or visual polish.

Suggested time: 1-2 days | Stack: React Native + TypeScript + Redux Toolkit

What to build

A simple store where users can browse products, view product details, add items to a basket and complete a basic checkout flow.

Screens

• Products - show a list of products with image, name and price.

• Product details - show more information and allow the item to be added to the basket.

• Basket - show selected items, quantities and the total price.

• Checkout - collect a few customer details and show an order confirmation.

Core behaviour

• Add products to the basket.

• Increase or decrease quantities.

• Remove products from the basket.

• Show the basket item count and total price.

• Prevent quantities from dropping below one.

• Show sensible empty states.

Redux Toolkit

Use RTK for the basket state. Include a configured store, a basket slice and typed hooks.

• addToBasket

• removeFromBasket

• increaseQuantity

• decreaseQuantity

• clearBasket

Use selectors to calculate the total number of items and total price. Do not store values that can be calculated from the basket.

A few expectations

• Use TypeScript and functional components.

• Use navigation between screens.

• Break the UI into sensible reusable components.

• Use FlatList for the product list.

• Add basic form validation at checkout.

• Include a short README with setup instructions.

Starter data

Use a local array of around 6-10 products. Each product only needs an id, name, description, price and image URL or local placeholder.

Stretch ideas: product search or filtering, basket persistence with AsyncStorage, discount codes, loading states, tests for the reducer/selectors, or replacing local products with RTK Query.

Done means: a user can browse products, add and update basket items, see accurate totals, complete the checkout form and reach a confirmation screen.

Quick start with Expo and the iOS Simulator

1. On a Mac, install Node.js and Xcode. Open Xcode once and make sure an iOS Simulator runtime is installed.
2. Run npx create-expo-app@latest mini-shop --template blank-typescript, then cd mini-shop.
3. Start the project with npx expo start, then press i in the terminal to open it in the iOS Simulator.
4. Install packages as needed, for example @reduxjs/toolkit, react-redux and React Navigation. Expo Go does not need to be installed separately for the simulator.
